Project abridged description

Growplify is a mobile application that uses AI to analyse company financial data and show if employees, teams and projects are generating profit or not. It creates financial reports and helps the user plan project outcomes based on different investment scenarios.

Chosen functionalities and tasks:

- Individual and team profitability analysis: I want to select the marketing team to see the financial return analysis according to the associated costs, and view the members individually.
- Profit forecasting and investment simulation: I want to simulate the profit of the website development project by decreasing the time invested and increasing the number of workers.
- Smart notifications: The marketing team's financial return fell by 8% last month, and therefore I want to receive a notification to alert me before it causes greater damage to the company.

Prototype’s Wireflow

The following images show how the “Profit forecasting and investment simulation” functionality works, specifically the “I want to simulate the profit of the website development project by decreasing the time invested and increasing the number of workers” task.

This would be the most important and complex task, as it uses AI tools to predict the project's profit by varying its variables through user input, which utilizes sliders for an intuitive interaction that allows visualization of the forecast in real time.

The following images show the interaction with the app, from the main page to the updated profit forecast.

Summary of Heuristic Evaluation results

Based on the heuristic evaluations received, the following problems were identified:

Visibility of system status - Graphs only show one value on the Y-axis, making it difficult to read values at other points.

Match between system and the real world - Project icons do not clearly represent the theme of the projects.

User control and freedom - The user cannot manage notifications.

Help and documentation - There is no help section, FAQ, or support.

Analyzing the points above, we notice that there are no very serious problems, but they deserve attention and need to be corrected.

Summary of corrections to perform in Phase 3

Taking into account the problems described previously, we have arrived at these possible corrections to be made in the next phase.

- Add more values to the Y-axis of the chart to improve data readability.
- Change the project icons to better represent the project themes, making them easier to identify.
- Add notification management with actions such as delete and mute.
- Create a Help, FAQ, or documentation section to support users.
